

Billboard's Top 100

Data Background:

This dataset includes data on every song that was in the Billboard's top 100 from August 1958 to January 2025. It was created by Chris Dalla Riva. It has multiple variables including Songs, Artists, Overall Ratings, etc.

Visualizations:

1.

1. This visualization shows the top 10 parent labels and their number of songs. It is from smallest to largest and filtered by the top 10. The x-axis represents the 10 parent labels and the y-axis represents the number of songs. Each bar represents the total count of songs that is connected with each parent label. We can see that Sony and Warner Bros account for a good amount of

songs with Vivendi being 3rd. This shows this distribution of songs among the parent labels. It is not evenly distributed as we can see that big names like Sony and Warner Bros. dominate slightly compared to other parent labels. Other companies contribute to being in the Top 100 but Warner Bros, Sony and Vivendi make up a good chunk of songs in the top 100 for parent labels. This can help us see the relationship between parent labels and how many songs reach Billboard's Top 100. There is a correlation between bigger companies having more songs but this could be due to the company having more artists.

2.

Relationship between Date and Overall Rating

2. This visualization shows the relationship between the date of the songs and the overall rating. It is a scatterplot and we can see there is no linear trend between the date and overall rating of the song. The x-axis represents the date and the y-axis represents the overall rating from 0 to 10. The ratings are scattered across the scatterplot. The ratings have no clear pattern which means that the songs don't really have a correlation in terms of how well a song is depending on the decade/date. This means that there are songs with high ratings in an older time and also high ratings in the present. Song quality does not decrease or increase over time. While popular music industries have changed in recent years, the

quality and ratings of these songs are consistent and do not appear to increase or decrease due to the time. This means that the songs are still considered good or bad even though the time may be different.

3.

3. This visualization shows the number of number 1 songs in the Billboard Top 100 by the artist's country of origin. On the x-axis we have the country of origin and on the y-axis, we have the number of songs. It is ordered from smallest to largest. We can see that the top two are the United Kingdom and the United States with the United States being the dominant place of origin. This visualization shows the distribution and how the United States has the most number one songs and this can be due to the popularity domestically as well as English being the most spoken language in the world. We can also see some of the other names having two locations and one of them is also the United States.
